

Figure 6 — DeepScience, native human panel against ortholog-remapped mouse panel. Every number carries coverage / denoise / anchor / panel / seed configuration. Panels (a) and (b) on H1 are at random\_state = 0, which under PI decision D-A is no longer H1's primary DeepScience estimator: directions are seed-robust, magnitudes are not.

(a) Caller agreement at full coverage, both arms, before and after conditioning on cell type × depth decile. No pair is at chance on either arm — the caller-independence claim is dead in both (PREREG §10.2). The circular pair is shown and is excluded from every pooled claim.

(b) P-ii, FALSIFIED. The published anchor is stable in 20/20 folds in all 7 H1 sections (stability 1.00 everywhere) and positive everywhere; on the remapped mouse panel it is not. (c) The instability transfers, and gets worse natively. Score agreement and call-set agreement are NOT the same quantity.

(d) P-vi, FALSIFIED. Registered: denoise=True RAISES the depth loading, as it does on 3 of 3 mouse sections. Falsifier:  $\Delta\rho \leq 0$  in  $\geq 5$  of 7. Measured on H1:  $\Delta\rho \leq 0$  in 6 of 7, and the SIGN of the loading inverts in 4 of 7. The mouse direction does not transfer.
